

## **The Appraisal of Liquid Fuel Refineries**

### **1 The Appraisal of Liquid Fuel Refineries**

2

3 Liquid fuel refineries (petroleum oil, ethanol, and biodiesel) present interesting appraisal  
4 problems. Their various technologies and the individual plants differ as much as the vehicles  
5 that use the refined fuel. Liquid fuel refineries can range in value from billions of dollars to  
6 being substantial liabilities. Their markets are peculiar: being dependent on several volatile  
7 commodity prices, subject to a mix of market and regulated affairs, impacted by international  
8 markets, and even contingent upon the weather. In this article, the issues, methodologies, and  
9 practice of appraisal of liquid fuel refineries will be examined.

10

### **11 The Economic Nature of Liquid Fuel Refineries**

12

13 It is an understatement that the modern economy requires liquid fuels. Liquid fuels have an  
14 unmatched energy density that even the best electric and natural gas vehicles cannot currently  
15 match. For over a century, those liquid fuels have been gasoline, diesel, aviation fuel, heating oil  
16 and heavy fuel oils. Recently, ethanol and biodiesel have gained a small market share as  
17 transportation fuel.

18

19 Economically, liquid fuel refineries convert commodities into other commodities and earn a  
20 profit when the spread between the two is advantageous. The technologies convert one form of  
21 chemical energy (crude petroleum oil, corn or vegetable oil) into another, namely gasoline,  
22 diesel, ethanol, or biodiesel. Numerous other co-products are also produced, and these can be  
23 substantial sources of revenue.

## The Appraisal of Liquid Fuel Refineries

24

25

### Main Sources of Gross Revenue for Fuel Refineries

<u>Petroleum Refineries</u>	<u>Ethanol Refineries</u>	<u>Biodiesel Refineries</u>
Gasolines	Ethanol	Biodiesel
Diesels	Distillers Grains	Sustainable Aviation Fuels
Aviation Fuels	Corn Oil	Glycerin
Heating Oils	CO2	RINs
Kerosene	RINs	Tax Credits
Lubricants	Tax Credits	
Aromatics		
Heavy Distillates		
Propane		
Butanes		
Naptha		
Asphalt		
Petroleum Coke		
Numerous Others		

26

27 The chemical conversion is completed by using large, expensive, and complex plants. Petroleum  
28 refineries are highly engineered. They frequently have values ranging from \$100's million to  
29 billions of dollars. In the United States, the national fleet of approximately 130 petroleum  
30 refineries has a wide range of technologies and effective ages; thus, it is difficult to compare one  
31 to another. The national fleet of approximately 225 ethanol refineries is also highly engineered.

## **The Appraisal of Liquid Fuel Refineries**

32 They frequently have values ranging from \$10's to \$100's millions. Interestingly, many of the  
33 recently constructed ethanol refineries in the United States are of similar designs and technology;  
34 thus, ethanol refineries can be more mechanically similar. Biodiesel refineries have substantially  
35 simpler engineering and are smaller in scale, frequently having values ranging from \$0.1 to \$10's  
36 million, with designs that are usually of custom, one-off plants. Currently, there are several very  
37 large biodiesel plants in development or recently completed that have values in \$100's millions.

38

39 There are other types of plants, such as breweries and alcohol refineries for human consumption,  
40 methanol plants, pharmaceutical fermentation plants, distillation plants, and others, that have  
41 similar major components and processes. While these won't be covered specifically in this  
42 article, their valuation process is similar.

43

### **44 The Spread**

45

46 As mentioned, fuel refineries profit when the spread in prices between their feedstocks and  
47 products is sufficiently positive. For example, the ethanol refining market pays close attention to  
48 the spread in prices between ethanol, their main product and corn, their main feedstock. This  
49 spread at ethanol plants and biodiesel plants is called the "crush spread". For petroleum  
50 refineries, it is called a "crack spread". Spreads can be thought of as a form of arbitrage. When  
51 the price of ethanol decreases and the price of corn increases, then the crush spread declines.

52 Fuel refineries likewise often work on narrow margins; the price of their main feed stock is  
53 relatively close to the price of their main products. Thus, small swings in spreads occasionally  
54 wipe out all profit in the short term. If today, corn prices rise and ethanol prices do not, profit

## The Appraisal of Liquid Fuel Refineries

55 could be temporarily wiped out. Conversely, if the spread increases, profits could increase  
56 dramatically.

57

58 When feed stock prices are sufficiently lower than the price of refined products, it is financially  
59 feasible to operate the plant. It should be noted that the spread must be sufficient to cover all  
60 other fixed and variable expenses, capital expenses, interest, taxes, and profit, and after  
61 consideration of other plant related incomes. Given that the other incomes and expenses are  
62 frequently less volatile, and frequently represent a relatively small portion of the income or  
63 expenses, prudent management focuses on the larger, harder to forecast ones, namely the main  
64 feedstock and product commodities. Thus, the industry focus is on spreads.

65

66 The prices of commodities are highly volatile. As commodities, crude oil, corn and vegetable oil,  
67 and fuel prices can change daily, and frequently do so, dramatically. While an insufficient  
68 spread is undesirable, it is a regular condition of the fuel refining market. It is a primary  
69 challenge for refinery appraisals to forecast these commodities into the short, intermediate, and  
70 long terms in order to forecast the spreads. It must be determined if the spreads will be negative  
71 in the long term, or whether profitability and value will be positive in the long term. If the net  
72 present value of the incomes (losses) from the periods with insufficient spreads is less than net  
73 present value in periods with sufficient spreads, then a refinery has positive value and is  
74 financially feasible to continue to operate. Of course, a substantially higher NPV is required to  
75 be financially feasible to construct. Regularly, refineries find that their spreads cannot support  
76 their construction debt but can support continued operations. This causes obsolescence.

77

# The Appraisal of Liquid Fuel Refineries

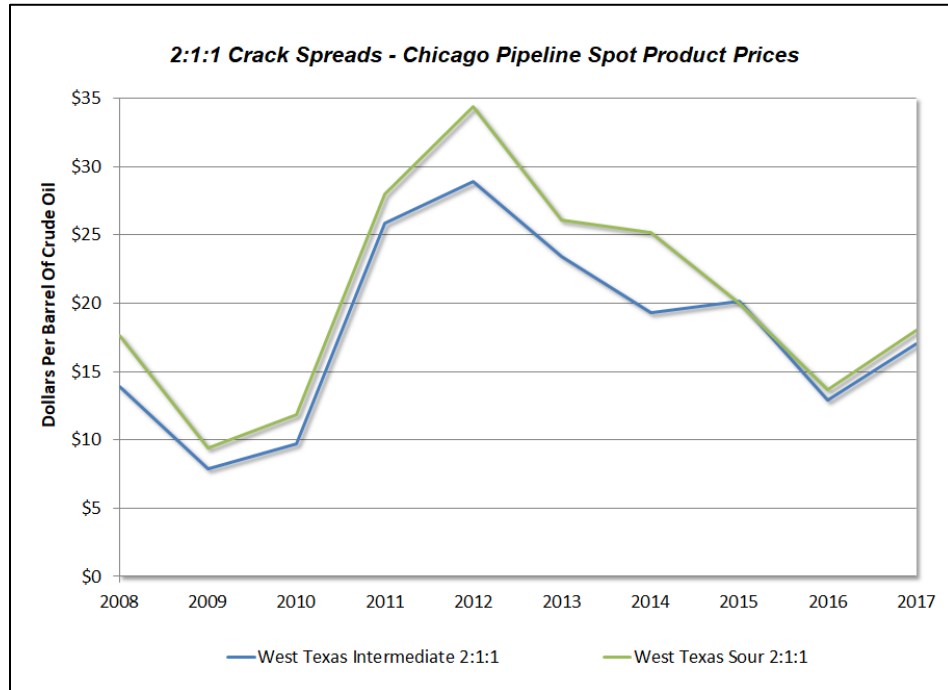

79

## Exhibit 1 - Historical Spreads

80

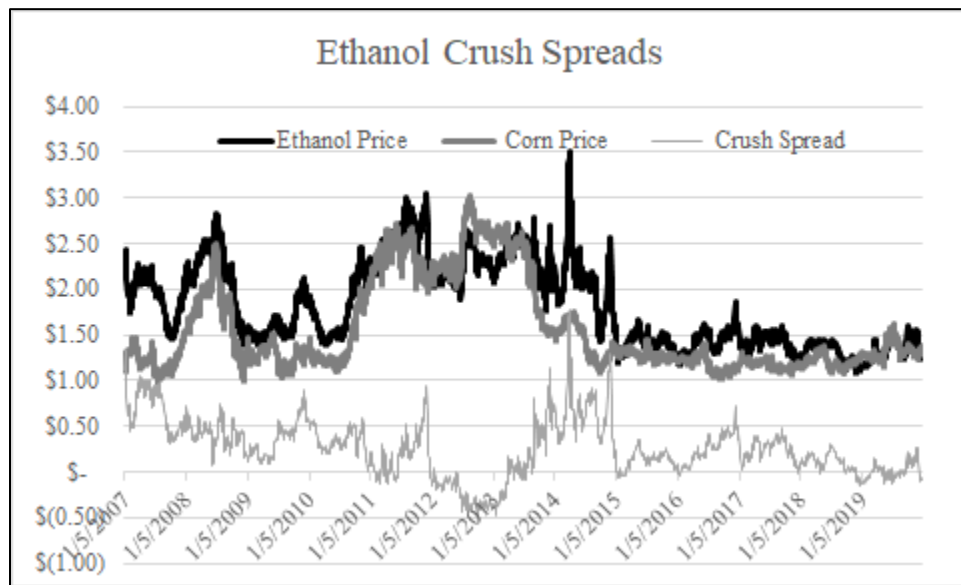

81

### Petroleum Refineries

82

83

84

85

## **The Appraisal of Liquid Fuel Refineries**

86 Decisions to operate, or not to operate, a fuel refinery must be made as commodity prices  
87 change. Refinery management complete their spread analyses sometimes daily. Unlike most  
88 general real estate, where it is extremely rare for prudent management to withhold renting space  
89 for temporary periods due to low market rents, fuel refineries sometimes prudently withhold  
90 production due to low spreads. In effect, at those times the highest and best use analysis for  
91 these plants fails the test for financial feasibility, hopefully only temporarily; however, this may  
92 indicate economic or functional obsolescence. Some financial infeasibility periods are to be  
93 expected at some refineries and fall within the range of long-term economically feasible and  
94 functional plants. In marginal cases, a refinery may accept a spread that's merely sufficient to  
95 minimize losses, until the long term-expected healthy spread returns. Since the decision to  
96 operate or not operate is an option, some refinery managers and appraisals conduct option  
97 valuations, such as Monte Carlo simulations to aid in decisions to accept short term losses in  
98 favor of longer-term larger profits.

99

## **100 The Units of Comparison**

101

102 Given that fuel refinery operations and capacities range over several magnitudes, values and  
103 incomes may be denominated in \$ millions to \$ billions. Rates of value may be expressed as  
104 dollars or cents. For example: \$/day, \$/year, ¢/lb, \$/ton, ¢/gal and others. There is a constant  
105 risk of miscommunication, that data between sources is not on the same basis when being  
106 considered by appraisers. The most discussed units of rating, comparison, and value for fuel  
107 refineries are usually expressed as volumes and weights (barrels, gallons, bushels, or tons, e.g.,  
108 \$/ barrel, barrels per day, \$/gallon, gallons per year, tons/year, \$/ton). But given the numerous

## **The Appraisal of Liquid Fuel Refineries**

109 components of these technologies within these complex plants, there are other possibilities, such  
110 as BTUs, cubic feet, and watts.

111  
112 Petroleum refineries are usually described as barrels/day of throughput or production. Ethanol  
113 and biodiesel refineries are usually described as million gallons/year. These rating figures are  
114 often found on the nameplates of major refinery elements, but also importantly, may be officially  
115 reported to or even measured by government agencies. These capacities sometimes change over  
116 time.

117

### **The Process of Fuel Refining**

118

119  
120 The various technologies for fuel refining have vastly different processes. Additionally,  
121 experimental technologies are regularly arising or in development, such as cellulosic ethanol. In  
122 a basic sense, however, refineries chemically alter compounds.

123

124 Fundamentally, petroleum refineries conduct distillation, cracking, and catalytic processes.

125 Petroleum refineries take the long-chain chemical compounds in crude oil, fracture it into smaller  
126 compounds, combine smaller compounds into preferred larger compounds, sometimes add other  
127 chemicals, and separate them into various products. Since crude oil is such a complex mixture of  
128 compounds, petroleum refineries regularly generate dozens of grades and products. Each  
129 petroleum refinery is specifically designed to first, process certain qualities of crude, and  
130 secondly, produce a certain array of products. When it comes to processing, there are three main  
131 types of petroleum refineries; topping, cracking, and coking, which represents a spectrum of

## The Appraisal of Liquid Fuel Refineries

132 capabilities to divide the crude into more and higher value products. The higher value products  
133 are typically gasoline, diesel, and aviation fuels depending on the market area. Asphalt is  
134 typically a less valuable product, but in most markets there is demand for some amount of  
135 asphalt. The first table in this article, Main Sources of Gross Revenue, lists products in loose  
136 order of value to a refinery. The challenge is to position the refinery to meet the market demand  
137 for each product. However, since building the units and components necessary to make a refined  
138 product can cost anywhere from \$10 to \$100 million and years to plan and build, missing the  
139 market can create significant obsolescence.

140

141 There are a variety of types of crude oil in the world. Of course, there is an expense to  
142 transporting it and many plants are generally designed to process crude geographically closer to  
143 the extent that it is profitable. Plants often blend different crude feedstocks in order to meet  
144 environmental standards and work around their plant's limitations. Some petroleum refineries  
145 process more heavy sour crude (higher density crude with more sulfur and other undesirable or  
146 problematic elements and compounds). Other petroleum refineries are capable of only processing  
147 limited sour crude and must process light sweet crude (crude with less sulfur and undesirables).  
148 West Texas Intermediate (WTI) is a light sweet crude. WTI is a common benchmark price. The  
149 challenge is that while heavy sour crude is cheaper, heavy sour crude refining is more expensive  
150 and capital intensive. The expense comes from the need to enhance plant construction,  
151 complexity, environment controls, and higher operating costs.

152

153 Ethanol refineries have a two-stage process, a biological and then a chemical stage. In the  
154 United States, fuel ethanol is typically produced by first processing corn into starch and then into

## The Appraisal of Liquid Fuel Refineries

155 sugar. The process continues with a biological process, fermentation, as is done with wine or  
156 beer where yeast converts the sugar into alcohol. Ethanol and alcohol are the same, except for  
157 the flavorings. Wine and beer are about 90% to 95% water, 10% to 5% ethanol, respectively,  
158 and with trace amounts of flavoring chemicals. After the fermentation stage, the alcohol is  
159 separated from the water largely by distillation. This is the same process that is used to make  
160 whiskey and moonshine, except that many whiskeys are distilled to only about 50% alcohol. If a  
161 still or refinery succeeds in removing most of the flavorings when at about 50% alcohol, the  
162 product would taste like a good vodka or grain alcohol. Fuel ethanol is distilled and further  
163 processed to almost 100% alcohol. In one of the last steps in preparing fuel ethanol, the product  
164 is denatured as required by federal law, typically by adding naphtha gasoline, in order to prevent  
165 the illegal sale of fuel ethanol for alcohol consumption.

166

167 Biodiesel refineries are substantially less complex and often have no or few high pressure or high  
168 temperature systems. Basically, a vegetable oil is mixed with methanol and the solution sits until  
169 the diesel separates by the forces of gravity from the other main product, glycerin. In the United  
170 States, the main feedstock for biodiesel is soybean oil, but any other vegetable oil can be used,  
171 and many small processors and hobbyists use old French fry oil from restaurants. Biodiesel  
172 refineries often require little to no exotic designs or materials.

173

### 174 Regulation

175

176 Fuel refining is not a regulated utility industry, unlike natural gas or electricity distribution  
177 utilities; however, many aspects of fuel refining are highly monitored for national strategic

## The Appraisal of Liquid Fuel Refineries

178 economic, security, safety and environmental reasons. Petroleum plant owners must report  
179 production and consumption activities to federal agencies. National fuel and consumption  
180 standards apply. Ethanol and biodiesel producers often receive incentives, while petroleum  
181 refiners often pay these incentives.

182

### 183 Cost Approach

184

185 The size of liquid fuel refineries ranges over several orders of magnitude, with small biodiesel  
186 plants in the 10,000 gallons per year capacity range, modern ethanol plants in the 100,000,000  
187 gallons per year, and petroleum refineries average in the 100,000 barrel per day range.

188 Refineries benefit from economies of scale, where concepts like cost-to-capacity<sup>1</sup> and the rule of  
189 six-tenths factor<sup>2</sup> can be generally applicable to the costs to build and to the operating incomes  
190 and expenses.

191

192 Still “bigger is better” has limits. For example, corn ethanol and biodiesel plants have been  
193 known to consume so much feedstock within their drive-time radius/market area, that they have  
194 caused feedstock prices to inflate so high as to destroy their crush spreads. Nationally, between  
195 2001 and 2009, a large number of new ethanol plants were built, and the new demand for corn  
196 caused large price spikes (see graph below). This caused severe economic obsolescence for a

---

<sup>1</sup> Valuing Machinery and Equipment: The Fundamentals of Appraising Machinery and Technical Assets, Third Edition by Machinery and Technical Specialties Committee of the American Society of Appraisers, Pages 51-52.

The costs of similar plants or pieces of equipment of different sizes vary, along a curved line, with the size raised to some power;  $Cost_B = Cost_A * (Size_B / Size_A)^X$ , where  $Cost_B$  equals the approximate cost of item having  $Size_B$ ,  $Cost_A$  equals the known cost of item having corresponding  $Size_A$ .

<sup>2</sup> The rule of six-tenths factor:  $Cost_B = Cost_A * (Size_B / Size_A)^{0.6}$ . The factor of 0.6, six-tenths, is so commonly utilized in budgeting and valuation, within the cost to capacity formula, that it has been given its own name.

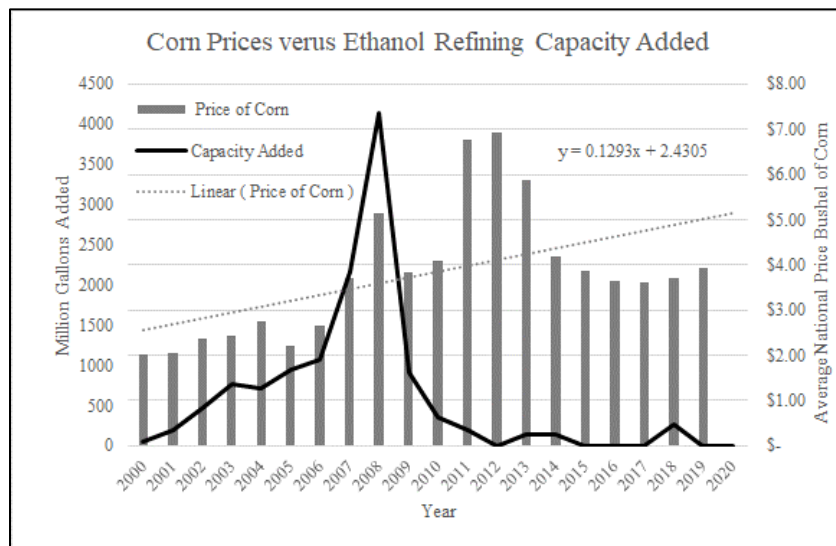

## The Appraisal of Liquid Fuel Refineries

197 period, which resulted in bankruptcy at some plants. The under-supply has since declined  
198 somewhat as farmers grew more corn to meet the new demand.

199

200

**Exhibit 2**

201

202

203 Each technology has its own economic life cycle. The components at fuel refineries are more  
204 like automobiles than general commercial real estate in that they usually have shorter, finite  
205 physical and economic lives. The major components often wear out within decades. Typically,  
206 these components are replaced or upgraded and the refinery continues to operate.

207

208 A good number of the petroleum refineries in the United State are between 50 and 125 years old,  
209 albeit with many new or renovated components. Sometimes, when major components wear out,  
210 it can render the balance of the plant fully depreciated, because the efficiency of new  
211 components at other plants make any old still-operable components financially uncompetitive  
212 even with some new components; its economically prudent to close the old refinery down. In  
213 1980, there were over 300 petroleum refineries in the United States. Today there are about 130

## **The Appraisal of Liquid Fuel Refineries**

214 operable petroleum refineries in the United States. The last fully new full capability petroleum  
215 refinery built in the United States was in 1977; however, interestingly, the total United States  
216 capacity has increased significantly in the last 20 years, as new capacity has been added to  
217 existing plants and outpaced the loss due to shut down capacity.

218

219 Most of the large ethanol refineries in the United States are of recent vintages. Ninety percent of  
220 current capacity has been built since 2000. Further, the recent technology is incomparably  
221 superior to the old. This leaves little long-term history on which an appraiser can base a life  
222 cycle opinion upon.

223

224 For these reasons, depreciation is preferably not estimated on the basis of the whole plant life,  
225 but instead on expected lives of each of the various components; however, this technique is only  
226 possible when data on the various components is available to the appraiser.

227

228 Petroleum refineries take 3 to 7 years to build. While no new fully capable grass-root plants  
229 have been built in decades in the United States, new petroleum refineries have been built  
230 internationally. Ethanol refineries take around 1.5 to 3 years to build. Biodiesel refineries take  
231 around 0.5 to 1.5 years, depending on whether existing finished general-purpose industrial  
232 buildings are utilized.

233

234 **Cost-Value Relationship and Disconnect**

235

## The Appraisal of Liquid Fuel Refineries

236 The basic concern surrounding the cost approach for fuel refineries is that typically the cost of  
237 construction of a new plant does not equal value. When applicable, the cost approach reflects  
238 market thinking by recognizing that market participants sometimes judge the value of a refinery  
239 by considering the cost to build the improvements; however, due to issues surrounding the cycle  
240 of the market, the age, condition, and legal status of the plant, simple, unadjusted cost is unlikely  
241 to equal market value. Unless the appraiser fully reflects all forms of depreciation (physical,  
242 functional, and external), then the cost estimate will diverge from market value. To make  
243 matters more difficult, the job of estimating each of the various forms of depreciation at fuel  
244 refineries is often problematic and sometimes practically impossible. Unlike general real estate,  
245 where a property frequently will continue to function if it is adequately maintained, even well-  
246 maintained fuel refineries may suffer critical economic and functional obsolescence. Common  
247 types of obsolescence include obsolete engineering designs and inefficiencies, operating cost  
248 inefficiencies (excessive operating costs, usually from new better technologies entering the  
249 market), obsolete environmental designs (legal/regulatory), original cost overruns, low spreads,  
250 and physical aging on a limited life span. Still the cost approach can be a viable approach to  
251 value, as the appraisal axiom suggests, because refineries are special purpose/built properties, but  
252 challengingly when significant depreciation and obsolescence is present or is difficult to  
253 quantify.

254

255

### Typical Overnight<sup>3</sup> Construction Costs

Petroleum	\$25,000/Barrel
Ethanol	\$2.10/Gallon

---

<sup>3</sup> Overnight costs do not include financing costs, entrepreneurial costs and other costs associated with the time to construct.

## The Appraisal of Liquid Fuel Refineries

Biodiesel \$1.50/Gallon

256

### 257 **Parts versus the Whole**

258

259 Fuel refineries are complex combinations of real property, personal property, and sometimes  
260 business intangibles<sup>4</sup> (as example, feedstock and fuel supply contracts or offtake agreements). A  
261 refinery is sometimes referred to as a business enterprise<sup>5</sup>, or a business combination<sup>6</sup>. The  
262 integrated combination of the total assets in the business creates the business enterprise. The  
263 market value of the total assets of the business (MVTAB)<sup>7</sup> is the value of the refinery as a whole,  
264 as an integrated combination. The components, such as real property (land, building), personal  
265 property, and business intangibles, are sometimes referred to as asset classes. The degree that a  
266 refinery consists of real property, personal property, or business intangibles is dependent on the  
267 definitions applicable in the appraisal context. It may be prescribed in law or regulation, but  
268 different circumstances will entail different law or regulations, and thus different definitions.  
269 For example, boilers or tanks may be considered to be real property in one state for ad valorem  
270 taxation, and personal property in another. They may also be classified as shorter- or longer-lived  
271 items for depreciation under state and federal law, investor reporting, or income tax reporting.

---

<sup>4</sup> **Intangible Assets** - Non-physical assets such as franchises, trademarks, patents, copyrights, goodwill, equities, mineral rights, securities and contracts (as distinguished from physical assets) that grant rights and privileges, and have value for the owner. The Dictionary of Real Estate Appraisal, Sixth Ed., Chicago, Appraisal Institute, Page 119.

<sup>5</sup> **Business Enterprise** - A firm or individual producing goods and services. An entity pursuing an economic activity. The Dictionary of Real Estate Appraisal, Sixth Ed., Chicago, Appraisal Institute, Page 28.

<sup>6</sup> **Business Combination** – Accounting Standards Codification (ASC) 805, Financial Accounting Standards Board (FASB). This standard directs the reporting of values for various classes and categories of property owned by business, tangible and intangible. The notion is that business is comprised of a combination of different assets and the value of important categories ought to be separately reported.

<sup>7</sup> **The Market Value of the Total Assets of the Business (MVTAB)**, The market value of all of the tangible and intangible assets of a business as if sold in aggregate as a going concern. The Dictionary of Real Estate Appraisal, Sixth Ed., Chicago, Appraisal Institute, Page 143.

## The Appraisal of Liquid Fuel Refineries

272 Despite these complexities, the refined product revenues are largely earned from all the assets  
273 equally as a business combination, because the various classes function best as one economic  
274 unit.

275

276 Depending on the use of the appraisal, there are occasions when the value of some real and  
277 personal property and business intangibles must be reported separately from each other and from  
278 the MVTAB. Many purposes require separate real and personal property values. For property  
279 tax appraisal purposes, the value of any tax-exempt property must be removed. For IRS and  
280 SEC reporting, the value of existing contracts might be separately reported from the rest. A  
281 residual technique is often the best method to isolate the value of the target assets from MVTAB.

282 In real estate appraisal, a land residual is where the overall real estate value ( $V_{l\&b}$ ) minus  
283 building value ( $V_b$ ) equals land value ( $V_l$ ). In refinery appraisals, the residual formula is  
284  $MVTAB (V_{refinery})$  minus value of assets that are not the subject of appraisal ( $V_{ns}$ ) equals the  
285 value of the balance of the plant ( $V_{bal}$ ), which is the appraisal target value of the subject  
286 property ( $V_s$ ).

287

288 The appraiser must exercise care to report which type of value is concluded as of each point in  
289 the appraisal. If the purpose of the appraisal is to report the value of something other than the  
290 MVTAB, as indicated by the income or sales approaches, then some further analysis beyond the  
291 MVTAB from the income or sales approaches will be necessary. The cost approach may or may  
292 not have been completed in a manner to indicate directly the target value to be appraised. If a  
293 unit in place cost approach was developed, then business intangibles were likely excluded, but  
294 real and personal property may still be intermingled, requiring further analysis. If a trended

## The Appraisal of Liquid Fuel Refineries

295 original cost approach was employed, it may have reported the value of real and personal  
296 property separately. Typically, the further analysis will include the use of various allocation<sup>8</sup>  
297 techniques. When used in conjunction with the sales and income approaches, the cost approach  
298 affords one of the best appraisal techniques to allocate MVTAB to the market value of the  
299 refinery's parts. Extraction<sup>9</sup> techniques are not typically utilized due to the lack of detail usually  
300 available in the market data.

301  
302 While sometimes problematic for estimating MVTAB, due do difficulties estimating all forms of  
303 depreciation, the cost approach is especially useful for appraising the different components of the  
304 refinery and for allocating value to the components of the refinery. The income and sales  
305 approaches on fuel refineries usually indicate MVTAB of the refinery rather than purely real  
306 estate or personal property values. MVTAB intrinsically reflects all forms of depreciation. Any  
307 residual or allocation using cost techniques, of MVTAB based on an income or sales approach  
308 for the refinery, will intrinsically reflect all forms of depreciation. For this reason, many refinery  
309 appraisers prefer to find value of components of a refinery via a residual or allocation of  
310 MVTAB, (a top-down approach), rather than building up a value via a cost approach (a bottom-  
311 up approach). Simply put, if an appraiser is to find a real and/or personal property value, it is  
312 often substantially easier to find MVTAB first and then complete a residual or allocation, than to  
313 complete a cost approach where there is great difficulty estimating all forms of depreciation.

---

<sup>8</sup> Allocation – A method of estimating land value in which sales of improved properties are analyzed to establish a typical ratio of land value to total property value and this ratio is applied to the property being appraised... The Dictionary of Real Estate Appraisal, Sixth Ed., Chicago, Appraisal Institute, Page 7. While written using land and building as examples, the underlying principle can be applied to parts of a business combination. Many appraisals for IRS and SEC reporting concerning purchase prices are completed using this concept, Purchase Price Allocations.

<sup>9</sup> Extraction – A method of estimating land value in which the depreciated cost of the improvements on the improved property is calculated and deducted from the total sale price to arrive at an estimated sale price for the land. The Dictionary of Real Estate Appraisal, Sixth Ed., Chicago, Appraisal Institute, Page 83. While written using land and building as examples, the underlying principle can be applied to parts of a business combination.

## **The Appraisal of Liquid Fuel Refineries**

314

315 Commonly, for property tax appraisal, excludable property may include inventory, pollution  
316 control improvements, contracts for feedstock supply, offtake agreements, specialized or  
317 proprietary documents (including policies and procedures, manuals, computer software, and  
318 drawings), and working capital accounts. As discussed earlier, the cost approach is usually the  
319 best method to estimate the value of the excludable tangible property. The value of inventory,  
320 specialized, or proprietary documents are usually estimated via cost techniques. Contracts are  
321 usually appraised via a comparison of the plant income streams with and without the contracts, in  
322 the same way that a leasehold analysis compares fee simple income streams to leased fee income  
323 streams.

324

### **325 Reproduction vs. Replacement Approaches**

326

327 Both of the two main cost methods, reproduction cost and replacement cost, are regularly applied  
328 to fuel refineries.

329

### **330 Trended Original Cost Method**

331

332 Although rarely utilized to value general real estate, the trended original cost method (TOC), a  
333 type of reproduction approach, is frequently utilized for complex special-purpose heavy  
334 industrial assets, like refineries. Historical cost information, even if decades old, is sometimes  
335 available on fuel refineries. In a TOC, the reproduction cost new (RCN) is computed by trending  
336 the original (historical) construction costs to the date of appraisal. The usefulness of the TOC

## **The Appraisal of Liquid Fuel Refineries**

337 method is contingent on the accuracy and completeness of the historical cost information. The  
338 costs by date of expenditure must be reliable and available for each class of asset within the  
339 entire plant, and must also include capital expenditures made since original construction, and  
340 include data on component retirements made through history.

341  
342 Various widely accepted cost trend references provide the basis for the trending of refinery  
343 construction costs. The indices do not give prices for specific cost items in either the historical  
344 period or the current period. Rather they provide the change in cost, the delta, between the  
345 different dates. Appraisers apply that delta to the actual original cost at the subject plant to get  
346 an RCN as of the appraisal date. The proper indices can be applied to specific cost items, such  
347 as bricks, tanks, or pumps, or to whole categories of refinery items, such as a boiler or distillation  
348 system.

349

### **350 Cost per Capacity Method**

351

352 The cost per capacity method, a replacement cost approach, is estimated by multiplying unit cost,  
353 usually \$/barrel or \$/gallon of capacity, by the number of units at the subject plant. The unit cost  
354 can be developed from a variety of sources including research publications, government  
355 estimates, contractor estimates, manufacturer estimates, owner estimates, or the comparative-unit  
356 method.

357

358 The cost per capacity method is relatively practical and is utilized by market participants because  
359 of its simplicity and availability; however, the apparent simplicity of the cost per capacity

## **The Appraisal of Liquid Fuel Refineries**

360 method can be misleading. This method is often less precise than others. It is sometimes  
361 difficult to reconcile the vast differences between the various cost sources and the subject plant,  
362 and between this cost approach and the other approaches. Few new refineries have been built  
363 recently, on which to base a cost per capacity estimate. At petroleum and biodiesel refineries,  
364 the plants are frequently of unique designs.

365

### **366 Physical Depreciation**

367

368 Typical depreciation techniques can be as simple as a single age-over-life ratio, or as  
369 complicated as the breakdown of the subject's assets into their various components for individual  
370 consideration. Models based on the economic age-life method are commonly utilized. For  
371 petroleum refineries, provided the scope of appraisal work allows, the age-life method is applied  
372 to plant components, and not a refinery-wide technique. Physical deterioration can be estimated  
373 by the straight-line method, and by the age-life method, using mortality dispersion techniques.  
374 Often the effective age plus the remaining useful life is equivalent to the service life.

375 Accounting and bookkeeping lives are not appropriate for appraisal purposes for fuel refineries.

376 Physical life may be longer than the average service life, but it may not accurately represent the  
377 usefulness of the service of an asset due to economic or legal reasons. The effective age should  
378 reflect the conditions of the plant, which often are not the chronological (actual or historical) age.

379 It should also be recognized that the expected remaining service life of a plant might change  
380 during its life for economic or legal reasons. This blurs the distinction between physical  
381 depreciation, and functional and economic obsolescence.

382

## **The Appraisal of Liquid Fuel Refineries**

383 With this said, these plants and their components are more like automobiles, which after so many  
384 proverbial miles get worn out. Many of the country's large ethanol and biodiesel plants are only  
385 about 10 years old. We have little historical record of full life cycles with these newer vintage  
386 technologies. Consequently, appraisers frequently approximate life and depreciation based on  
387 engineered design life.

388

389 Conversely, some of the country's petroleum refineries are approaching 100 years of age, where  
390 major additions and replacements subsume the remaining original parts with the current plant  
391 bearing little resemblance to the original plant.

392

### **393 Functional Obsolescence**

394

395 Functional obsolescence is common at petroleum fuel refineries and is often easily spotted. It  
396 usually arises as a result of the ad hoc additions and renovations to the plants over their many  
397 decades. Functional obsolescence is less common at the new ethanol and biodiesel plants, as  
398 they often represent state of the art designs, built at the same time in an integrated fashion.  
399 Petroleum refinery managers and engineers will be aware of the limitations and are usually quick  
400 to accurately report the issues. The types of functional obsolescence commonly found include  
401 deficiencies requiring an addition, deficiencies requiring a modification, deficiencies requiring  
402 additional operating costs, and super-adequacies. Often these deficiencies are incurable, in both  
403 the short and long term, but deferred maintenance can also be present Appraisers will expend  
404 considerable effort on determining the value lost to functional obsolescence. A common  
405 technique for the appraiser is an income and expense analysis, with and without the

## **The Appraisal of Liquid Fuel Refineries**

406 dysfunctional issue. Despite this, this approach may be problematic if it causes a circular  
407 argument between the cost and income approaches, leaving the cost approach as not fully  
408 independent from the income approach.

409

### **410 Economic Obsolescence**

411

412 Economic obsolescence within fuel refinery industry occurs regularly. Changes in federal or  
413 state law, the economy, and/or any operational constraints external to the asset can cause  
414 economic obsolescence at fuel refineries. One cause of economic obsolescence is unfavorable  
415 spreads in commodity prices or unfavorable crack or crush spreads. Usually, the impact on value  
416 can be measured by capitalizing the expected losses in earnings over the period that the condition  
417 is expected to persist. If the economic obsolescence is not permanent, still the appraiser must  
418 determine if the net present value of future positive spreads nets out to something financially  
419 feasible against the cost of maintaining the plant until spreads recover. For example, historically  
420 several ethanol and biodiesel plants closed permanently in the late 2000's because at that time,  
421 spreads were not expected to support financial activities for a period of years and the cost of  
422 maintaining the plant in the interim was too high to justify waiting for the future value of the  
423 recovered market years later. Some of those refineries were liquidated as parts and scrap.

424

425 Common techniques used for estimating functional and economic obsolescence include the  
426 capitalization of excess operating costs and the capitalization of income shortfalls. In both,  
427 income capitalization techniques are employed to evaluate the loss in value from specific  
428 operating or capital costs, or from an inability to earn income. While not adequate to measure

## **The Appraisal of Liquid Fuel Refineries**

429 the value of the obsolescence, the existence of functional and economic obsolescence is often  
430 easily discovered by comparing MVTAB from the income and sales approaches to the  
431 replacement cost new less physical depreciation (RCNLD). Any difference can be attributed to  
432 either functional or economic obsolescence or both. While this comparison proves the existence  
433 of the obsolescence, this direct comparison of values from income and sales approaches to value  
434 from the cost approach is a circular measurement of the amount of obsolescence. Such a circular  
435 determination could spoil a cost approach as an independent approach from the sales or income  
436 approaches, and is not acceptable in many courts.

437

438 Half of the petroleum refineries in the United States have been retired since 1980. These retired  
439 facilities were judged to be financially infeasible for physical, functional, and economic reasons.  
440 At this time, there is little expectation that the remaining petroleum refineries will be retired soon  
441 though history shows it is common to have one or two refineries permanently shutdown ever  
442 year.

443

## **444 Land and Real Property Values**

445

446 There are often numerous high quality, heavy duty industrial buildings at petroleum and ethanol  
447 refineries, representing a considerable aggregate building value relative to many general  
448 commercial properties in the area. Still, the land and overall real property at petroleum and  
449 ethanol refineries often contributes little, relatively speaking, to MVTAB. At petroleum  
450 refineries, the machinery is simply massive and extensive. Petroleum refineries are frequently  
451 located on larger parcels in older industrial areas, where the possibility of environmental issues is

## The Appraisal of Liquid Fuel Refineries

452 a concern. At ethanol refineries, the machinery while not as extensive as petroleum, is still  
453 relatively high value compared to the real property. Ethanol refineries are usually located in  
454 rural, low land value areas and are commonly developed on green field sites. Their total acreage  
455 and the cost of approvals and permits can be high, thus representing a high land value relative to  
456 many adjacent properties.

457

458 The machinery at biodiesel refineries is often common off-the-shelf technology and materials.  
459 Given that machinery at biodiesel refineries is a relatively smaller portion of the total property,  
460 plant and equipment, land value and overall real property at such refineries can represent a  
461 sizable portion of the MVTAB.

462

463 An across-the-fence method,<sup>10</sup> assuming highest and best use similar to the properties from  
464 “across the fence,” is typically employed to measure the value of the underlying land at  
465 refineries. The value of licenses, permits, and approvals for the refinery activity, which can be  
466 substantial, are generally accounted for in the soft cost of construction. These land parcels  
467 frequently have intermodal transportation features, which can add value but to a limited market.

468

469 The real property improvements can frequently be classified as industrial with support offices,  
470 and miscellaneous other types of space. There may be several types of industrial space with each  
471 deserving its own separate cost estimate, especially when some of the industrial space can be

---

<sup>10</sup> **Across-the-fence method** - A land valuation method often used in the appraisal of corridors. The across-the-fence method is used to develop a value opinion based on comparison to abutting land. The Dictionary of Real Estate Appraisal, Sixth Ed., Chicago, Appraisal Institute, Page 3.

## **The Appraisal of Liquid Fuel Refineries**

472 very large and for very heavy-duty industrial activities, while some support buildings at the same  
473 plant can be of fairly low value.

474

### **475 Sales Comparison Approach**

476

477 While the use of the sales comparison approach is common in the appraisal of general  
478 commercial properties, this approach is rarely probative in refinery appraisals. Research on sales  
479 of comparable fuel refineries rarely yields appropriate and adequate data for a credible sales  
480 approach. The market for fuel refineries is national and sometimes international. It is easy to  
481 find evidence of an active sales market; however, relevant critical details about the individual  
482 sales are often unattainable. An important qualification of each credible comparable sale is the  
483 level of supporting data that is publicly available. Since many details concerning the sales of fuel  
484 refineries are confidential, even though the sellers and buyers are often public companies, the  
485 sales are not adequately verifiable and/or cannot be soundly adjusted. Since fuel refineries are  
486 typically business combinations, the sales are for combinations of assets; real, personal, and  
487 business assets. Many sales include corporate (business) and personal property assets. Further,  
488 these transactions often include assets beyond the tangible refinery, such as investment  
489 participation, corporate financing, partial interests, off-take and supply contracts, and other  
490 valuable closing contingencies. Buyers and sellers are under no obligation to publicly report the  
491 portion of the price attributable to the parts of the total sales price in a format that is useful to  
492 appraisers. Information on the refinery or the real property portion of the price may be reported  
493 to state and local taxing authorities, based on an allocation of the refinery purchase price. In  
494 theory, that can serve as a basis of comparison in an appraisal, although some court cases point

## The Appraisal of Liquid Fuel Refineries

495 out limitations<sup>11</sup>. Publicly traded companies may report some details on the sale of a refinery.  
496 Again, in theory, that data can serve as a basis of a comparable in an appraisal. Unfortunately,  
497 this reporting often is still not complete enough. Therefore, while there is frequently available  
498 data to identify comparable sales, there is not sufficient public data in many cases to fully  
499 complete a credible appraisal adjustment process.

500

501 Lastly, many of the sales of refineries within the last decade are of financially troubled assets.  
502 Such sales were predominant at moments in the market, while other refineries did not sell or  
503 suffered financial collapse. The troubled sales are not reliable indicators for value under a going  
504 concern premise, but may be indicative of liquidation values.

505

506 Market condition adjustments are important as values for fuel refineries change frequently  
507 market-wide, due to macroeconomic conditions, including the general economy trend, feedstock  
508 and fuel price trends, regulations, and green energy trends. Since refineries are subject to the  
509 variability of commodities markets, their values are more volatile than general commercial real  
510 estate markets. Adjustments for physical characteristics are typically made for plant design,  
511 process type, unit size, capacity reliability, plant condition, age, super adequacy, functional  
512 utility, and remaining life; however, required adjustments for these factors often cannot be made  
513 reliably because many physical characteristics of the comparable sales are not released as public  
514 information. Location-based revenue differences should be analyzed, as feed stock and product  
515 prices are usually dependent on the location of each plant. Other locational differences may

---

<sup>11</sup> Mobile Telecommunications Technologies, LLC V. Sprint Nextel Corporation, Case No. 2:12-CV-832-RSP

## **The Appraisal of Liquid Fuel Refineries**

516 include the proximity and availability of pipelines, railroads, natural gas and electricity lines,  
517 water supply, and dockage. Additionally, adjustments related to income tax differences may be  
518 necessary, as taxes are an important factor in the MVTAB of refineries.

519

### **520 Income Approach**

521

522 Traditionally, income strictly attributable to the real property at general commercial real estate  
523 such as offices and apartments is ubiquitously prescribed by real estate leases or the market  
524 potential to be leased. Fuel refineries are very rarely rented. They are mostly owner occupied.  
525 When rented separately, the leases are usually part of structured financing that limits the lease's  
526 probative utility within appraisal. Biodiesel plants are smaller and often developed within  
527 conventional industrial buildings. The real property at biodiesel refineries is regularly rented.

528

529 Nonetheless, fuel refineries are income producing assets where the income is generated by the  
530 operation of the combination of real and personal property and any business intangibles. At fuel  
531 refineries, there is typically no credible and reliable way to isolate the income solely attributable  
532 to the real property, such as a lease. The income utilized in the fuel refinery income approach is  
533 from operation of the combined assets of the business enterprise. Such intermingling conditions  
534 also exist at many other types of commercial property, such as hotels, theaters, hospitals,  
535 telephone companies, water companies, landfills, and racetracks. Given this issue, the appraiser  
536 commonly first concludes an MVTAB based on the income of the plant, and then employs  
537 various appropriate appraisal procedures to separate out the value of the real and/or personal  
538 property, intangibles, or other target interest at the plant.

## The Appraisal of Liquid Fuel Refineries

539

540 Given the volatility of the commodities that drive the income and expenses at refineries, a  
541 discounted cash flow (“DCF”) analysis is preferred over a direct capitalization technique.

542 Additionally, since income tax consequences are distinct from time to time and from refinery to  
543 refinery, it essential, in most cases, to conduct after-tax analyses and comparisons. For example,  
544 the tax incentives play a major role in the feasibility of ethanol and biodiesel refineries. These  
545 are standard practices in the valuation of fuel refineries.

546

547 The holding period for fuel refineries is driven by physical considerations as well as legal,  
548 regulatory, and contractual conditions, and is often prescribed by common practice among  
549 market participants. The analyst looks to the finite remaining life of the plant to form the basis  
550 of the holding period. As such, it is common practice to assume a holding period equal to a  
551 plant’s estimated remaining economic life, with no reversion. Consequently, some discounted  
552 cash flow (“DCF”) analyses are projected as long as 35 years for ethanol refineries. Since  
553 history shows that petroleum refineries can have lives over 75 years, DCFs of 10 years with a  
554 reversion are most common.

555

### 556 **Reversionary Value**

557

558 A reversionary value is assumed in most DCF analyses for commercial real estate. This value  
559 captures the income generated from the asset after the end of the holding period and is typically  
560 calculated by utilizing a direct capitalization method and then discounting that value to the  
561 valuation date. This is true of most DCF analysis on petroleum refineries, because at this time

## **The Appraisal of Liquid Fuel Refineries**

562 most remaining petroleum refineries are expected to continue well into the future; however,  
563 unlike general real estate and petroleum refineries, ethanol and biodiesel refineries are expected  
564 to have relatively short, finite lives. When the holding period for a refinery is assumed to be  
565 equal to its remaining economic life, then there will not be a reversionary value for the plant at  
566 the end of the holding period. Assumptions made about disposition of the remaining assets (or  
567 liabilities) may be broken down in three categories: decommissioning liability, salvage and scrap  
568 value, and land value. Often, refinery appraisers conclude that the sum of the three reversionary  
569 considerations net to a zero value.

570  
571 When a direct capitalization method is completed, the cap rate must be adjusted upward to reflect  
572 the fact that the income and value may decline to zero over the holding period, since the  
573 reversionary value of a plant with a finite life is zero. It is common practice in refinery valuation  
574 to avoid this issue in DCF reversionary cap rates by setting the holding period equal to the  
575 plant's remaining economic life.

576

### **577 Supply and Offtake Agreements**

578

579 Plant owners regularly contract in advance to sell their products via long term offtake  
580 agreements, instead of selling their products in the daily mass markets. Similarly, plant owners  
581 regularly contract in advance to buy feedstocks, electricity, and natural gas, via long term supply  
582 contracts. These agreements fall into two broad categories; those that have contract prices for at  
583 or near market prices, and those that have contract prices at substantially above or below market  
584 prices. The reason that contract prices are substantially above or below market prices may be

## **The Appraisal of Liquid Fuel Refineries**

585 that 1) they are sometimes between related parties, 2) there might be more to the transaction than  
586 just the sale of the commodity, 3) they represent a business mistake, or 4) they are hedging  
587 contracts. These agreements do not meet the criteria of market-indicative transactions, and  
588 cannot be used to determine market value, but can certainly indicate the value of the going  
589 concern or value-in-use. This is analogous to appraising an office building which has inter-  
590 company leases or sale-leasebacks that were not based on market terms. If the purpose of the  
591 appraisal is to determine market value assuming fee-simple, value-in-exchange conditions, the  
592 atypical office leases are replaced with normal market-based terms.

593

### **594 Hedging Contracts**

595

596 Judging the significance of contracts that are above or below market is always difficult but even  
597 more so when the contracts represent hedging exercises that may be impacting the risk associated  
598 with the refinery business. Hedging is contracting over the longer term for steady supplies and  
599 prices at the cost of higher prices for the benefit of avoiding inadequate supplies and potentially  
600 very high spikes in prices. Hedging lowers risks associated with commodity volatility. While  
601 hedging may moderately increase prices, it preserves and may enhance value by decreasing risk.  
602 The fuel refining industry regularly hedges crude oil, refined petroleum products, corn, and  
603 natural gas.

604

### **605 Long and Short Term Trending**

606

## **The Appraisal of Liquid Fuel Refineries**

607 Unlike DCF forecasts for general real estate, which are commonly for ten years, refinery  
608 forecasts are regularly up to 35 years. The Consumer Price Indices (CPI) provide an excellent  
609 source for forecasting commodity and fuel prices, and the general expense rate of inflation over  
610 the very long term. The CPIs are well documented and refinery market participants often rely  
611 upon them. The data reveals several important trends. Generally, commodity inflation rates  
612 have not kept pace with general inflation over the decades. The general CPI is the average of all  
613 products and services, but there are indices specific to fuels and energy. Commodities, like  
614 crude and corn, trend at rates lower than other products and services in our economy, some of  
615 which (such as health care, college education) suffer more from inflationary forces.

616

617 In the short term, the appraiser ought not to assume current prices for inputs to an income  
618 approach are at long term trend line. These inputs concern commodities, which are volatile.  
619 Price trends for any given plant will be driven by local market conditions and will likely be off of  
620 long-term trends on a regular basis. Appraisers must examine local plans for plant retirements  
621 and new additions, as well as market constraints, and commodity supply and demand conditions.  
622 These local trends can cause local prices to trend in a dramatically different fashion than the  
623 long-term CPI trends, until a new market equilibrium is achieved.

624

625 Current prices and short- and long-term trends can be found in various government reports.  
626 Numerous financial data sources exist online. Also, there are several national forecasting  
627 services, such as Standard and Poors. Then, there are refining industry trade groups and  
628 consultants that provide information regularly utilized by appraisers.

629

## **The Appraisal of Liquid Fuel Refineries**

### **630 Fixed and Variable Expenses**

631  
632 Operations and maintenance (O&M) expenses are analyzed as is normally done in the appraisal  
633 of income producing properties, namely based on historical and comparable expenses, with one  
634 exception. Considerable special efforts are typically made to forecast feedstock and product  
635 commodity expenses, separate and apart from other O&M expenses. Also, parent company  
636 general and administrative expenses may need to be apportioned down to the subject plant, when  
637 the plant is owned and managed in a portfolio of plants.

638

### **639 Income Taxes**

640

641 Unlike nearly all appraisals of general real estate, refinery income approaches are usually  
642 completed after deducting income taxes. This is useful and often necessary for several reasons.  
643 A major contributor to the value of many plants is its effective income tax rate. Fuel refineries  
644 often have tax benefits, including accelerated depreciation, investment tax credits, exemptions,  
645 or others. Also, while traditional real estate appraisals are completed before income taxes and  
646 most of the theory and data in the real estate appraisal community is arranged for before income  
647 tax analysis, business appraisals are traditionally completed on an after-income tax basis. Most  
648 of the financial market data available for the appraisal of the fuel refining industry is on an after-  
649 income tax basis. Nearly all market participants appraise on an after-income tax basis. In  
650 theory, both before and after income tax appraisals should yield the same indication of value, but  
651 only when the tax benefits are fully and properly adjusted for. Another advantage of the after-

## **The Appraisal of Liquid Fuel Refineries**

652 income tax analysis is that the inputs and adjustments are explicit and thus, are available for  
653 easier review.

654

655 Capital expenses, depreciation, and interest expenses must be computed in order to compute the  
656 effective income taxes. Given the magnitude of capital expenses, prudent management budgets  
657 for them many years out. The appraiser ought to review cap ex history, as well as budgets.

658 Depreciation expenses should be calculated utilizing the modified accelerated cost recovery  
659 system (“MACRS”); however, simpler methods may be acceptable in some cases. The refining  
660 industry relies on debt financing. If the goal is to estimate market value, appraisers forecast the  
661 interest expense by applying industry/market-specific interest rates as of the valuation date to the  
662 portion of the plant’s value that is estimated to be financed with debt.

663

### **664 Capitalization and Discount Rates**

665

666 Theoretically, there are several possible methods for estimating capitalization and discount rates,  
667 including market surveys, extraction from market sales, and various mathematical financial  
668 formulas. Extraction from refinery sales very rarely yields sound or adequate data. Also, there  
669 are no surveys of refinery cap and discount rates. Therefore, rates are usually determined using  
670 well known financial formulas.

671

## The Appraisal of Liquid Fuel Refineries

672 Refinery appraisers frequently complete a formula-based analysis of discount rates known as the  
673 Weighted Average Cost of Capital<sup>12</sup> (“WACC”) in the business appraisal community. In the real  
674 estate appraisal community, this formula is recognized as a Band of Investment<sup>13</sup> formula. The  
675 major difference is that the Band of Investment formula is typically utilized to determine cap  
676 rates for real estate before income taxes, while the WACC is typically utilized for discount rates  
677 after income taxes. The basic elements of yield (or capitalization) rates are debt and equity.  
678 When combined, they indicate the overall investment yield. This cost of capital analysis is  
679 “weighted” because it incorporates the percentage of the total investment that debt contributes  
680 and the percentage that equity contributes, which is a weighted average concept.

681

682 Algebraically the WACC analysis is expressed in the following figure:

683

### 684 The Formulaic Derivation of an After Income Tax Discount Rate

#### 685 Weighted Average Cost of Capital (WACC)

686

$$687 \quad Y_o = (M \times Y_m \times (1-t)) + ((1-M) \times Y_e)$$

688

689 Where,

690  $Y_o$  = Overall Yield Rate

691  $M$  = Debt to Value Ratio

---

<sup>12</sup> Weighted Average Cost of Capital - The cost of capital (discount rate) determined by the weighted average, at market values, of the cost of all financing sources in the business enterprise’s capital structure. The Dictionary of Real Estate Appraisal, Sixth Ed., Chicago, Appraisal Institute, Page 248.

<sup>13</sup> Band of Investment - A technique in which the capitalization rates attributable to components of a capital investment are weighted and combined to derive a weighted-average rate attributable to the total investment. The Dictionary of Real Estate Appraisal, Sixth ed. Page 19. Chicago: Appraisal Institute, 2010.

## The Appraisal of Liquid Fuel Refineries

692  $Y_m =$  Debt Yield Rate

693  $Y_e =$  Equity Yield Rate

694  $t =$  Effective Income Tax Rate

695

### 696 **Equity and Debt Yields**

697

698 There are several well-developed theories and widely used effective methods for estimating the

699 equity cost of capital, including a build-up method and the Capital Asset Pricing Model<sup>14</sup>

700 (CAPM). The build-up method is an additive model in which the equity return on an asset is

701 estimated as the sum of a risk-free rate and one or more risk premiums. The risk-free rate is

702 usually long-term United States government bond yields. The risk premiums adjust for risks

703 associated with systematic and unsystematic risks, size and industry risk, illiquidity, managerial

704 effort, and others. The CAPM formula considers the sensitivities to non-diversifiable risk (also

705 known as systematic risk or market risk), often represented as a beta<sup>15</sup> coefficient. Like the

706 build-up method, it begins with the expected return of a risk-free asset and then adjusts for the

707 market-wide expected return. There is much literature on both the build-up and CAPM

708 formulas, and thus, they will not be covered further herein.

709

710 Debt rates are estimated the usual way with one exception: the pre-income tax debt rate is

711 adjusted for the ability to deduct debt interest expenses from income taxes, by multiplying the

712 cost of debt by one minus the income tax rate.

## The Appraisal of Liquid Fuel Refineries

713

### 714 **Working with Other Professions**

715

716 The refinery appraiser will frequently join with professionals from other disciplines in order to  
717 complete a refinery appraisal. Refinery appraisals often benefit from consultation with  
718 professional engineers. Further, refinery appraisers regularly use the services of commodity  
719 price forecasters. Other professionals may include regulatory experts, economists,  
720 mathematicians, attorneys, and accountants who have expertise in some element related to the  
721 appraisal problem at hand.

722

### 723 **Reconciliation of Value**

724

725 There are two considerations one must weigh when applying various approaches to value. First,  
726 appraisers should use those approaches commonly utilized by market participants<sup>16</sup>. Second, the  
727 supply of data within a market or within a particular timeframe may preclude the development of  
728 one or more of the approaches to value commonly employed in other appraisal practice areas or  
729 times. Generally, the sales comparison approach is not employed to determine the value of fuel  
730 refineries due to the lack of reliable public market data. Generally, the income approach is the  
731 primary method utilized by market participants, and is typically the approach prescribed by  
732 appraisal theory as being the most appropriate. Generally, the cost approach is of limited probity  
733 when issues of functional or economic obsolescence arise. If the refinery is in a healthy

---

<sup>16</sup> **USPAP, 2014**, Standards Rule 1-6, In developing a real property appraisal, an appraiser must: (a) reconcile the quality and quantity of data available and analyzed within the approaches used; and (b) reconcile the applicability or suitability of the approaches used to arrive at the value conclusion(s).

## **The Appraisal of Liquid Fuel Refineries**

734 economic market and time frame and is newer, the cost approach can be as strong an indicator as  
735 the income approach. Given that fuel refineries may be classified as special purpose properties,  
736 local law may emphasize or mandate one or more approaches to value.

737

### **738 Conclusion**

739

740 Appraising fuel refineries is a specialty practice and will require the utilization of infrequently  
741 employed appraisal theory and techniques, but in the end no new practices will be needed for the  
742 widely read appraiser.
